

BACKFLOW PREVENTOR WITH ADJUSTABLE OUTFLOW DIRECTION

ABSTRACT OF THE DISCLOSURE

5 A backflow preventor which permits adjustment of the
outflow direction is provided. A conduit provides fluid
communication between the two valves of the backflow preventor.
The conduit can be separated, e.g., by cutting along a groove,
leaving annular flat regions. The annular flats are configured
to engage with a coupler to provide leak-free connection
10 between the separated portions of the conduit. The separated
portions of the conduit can be rotated to adjust the outflow
direction. Preferably, an infinite number of outflow
directions are possible, all of which lie in a plane parallel
to the inflow direction.
